

# The idea

the idea must have JSON input & output. It's also got to be able to manage something to do with time. And if something near it must alert the user. My idea is simply a calendar with import export options. This can also be stored in local storage for continuity.

## Functionality

Display a calendar in multiple formats (e.g. day, week, etc)  
I do this so ~~the user~~ as this is the main purpose of the website

Notifications/banners for upcoming events

This is for the obvious; alerting the user of near tasks

Import/Export options for calendar.

This is for cross-device calendars. help consistency

Import events using .ics file.

Sharing certain events is so useful.

Create, edit, remove events. Obvious

local storage.

to keep a users calendar after close  
password/Auth (maybe?)

keep calendar private.
